With a diverse sample (N = 231 paired responses) of employees from various organizations in Pakistan, the authors tested for the main effects of perceived organizational politics and psychological capital on turnover intentions, job satisfaction, and supervisor-rated job performance. They also examined the moderating influence of psychological capital in the politics–outcomes relationships. Results provided good support for the proposed hypotheses. While perceived organizational politics was associated with all outcomes, psychological capital had a significant relationship with job satisfaction and supervisor-rated performance only. As hypothesized, the negative relationship of perceived organizational politics with job satisfaction and supervisor-rated performance was weaker when psychological capital was high. However, the result for turnover intentions was counter to expectations where the politics–turnover intention relationship was stronger when psychological capital was high.

Keywords: *perceived politics; psychological capital; job performance; job satisfaction; turnover intentions*

Over the past couple of decades, perceived organizational politics (POP) has remained an important subject of inquiry in the field of organizational behavior and is commonly viewed as a source of detrimental consequences for organizational members (e.g., Chang, Rosen, & Levy, 2009; Ferris, Russ, & Fandt, 1989). However, despite two recent meta-analytic studies, the effects of POP on outcomes are still inconclusive. For example, Miller, Rutherford, and Kolodinsky's (2008) meta-analysis examining perceived politics and various employee outcomes such as job stress, job satisfaction, turnover, and organizational commitment suggests that POP is generally detrimental to personal and organizational effectiveness, yet their findings also reveal variation in effects across outcomes and certain settings. Specifically, the effects for job performance were much smaller than for other outcomes, and public sector employees were more likely than private sector employees to leave the organization in the face of organizational politics. In addition, the effects for organizational commitment were much lower in international samples than in domestic samples, suggesting the need for further exploration of POP theory in different cultures to determine its boundary conditions.

Pointing to the lack of a theoretical understanding of how perceptions of politics influence employee outcomes, Chang et al. (2009) called for future researchers to examine contextual and individual difference factors as moderators in such relationships. Although few studies have attempted to explore the moderating role of individual difference variables in the relationship between perceived politics and various outcomes, there remains a lack of understanding of the influence of an individual's composite psychological resources, particularly hope and self-efficacy, on the relationship between perceived politics and outcomes such as turnover intentions, job satisfaction, and job performance.

For example, Kacmar, Collins, Harris, and Judge (2009) found that core self-evaluations (which include generalized self-efficacy) exacerbated the relationship between POP and job performance. Bozeman, Perrewé, Hochwarter, and Brymer (2001) found some mixed evidence whereby self-efficacy intensified the negative effects of perceived politics on job satisfaction; however, it did not moderate the POP–turnover intentions and POP–job stress relationships. On the contrary, we draw upon the conservation of resource (COR) theory (Hobfoll, 2011) to argue that psychological capital (PsyCap) comprising hope and self-efficacy will act as “a solid resource reservoir” (Hobfoll, 2002: 318) and reduce the negative effects of politics on work outcomes. Thus, the study of PsyCap as a holistic core construct will better explain the moderating role of such constructs in the POP–outcomes relationships and advance further knowledge in this domain.

In addition, it is important to note that the majority of studies in this domain of research have been conducted in developed countries of North America and Europe. Tsui, Nifadkar, and Ou (2007) suggested that unless we test the theories largely developed in the United States in non-Western settings, researchers and practitioners will have little confidence about their generalizability in other regions. We believe that our study addresses this gap, as it provides a rare opportunity to examine the applicability and validity of concepts largely developed in Western cultures.

Theory and Hypotheses

POP, PsyCap, and Workplace Outcomes

Politics, the perception of which varies from person to person, is an inevitable component of an organization's social fabric. Despite some discussion that some individuals thrive on politics, using it to their advantage through the development of political skill (Ferris, Perrewé, Anthony, & Gilmore, 2000), this treatment of POP has typically been made in reference to the upper organizational echelon of executives (see Perrewé, Ferris, Frink, & Anthony, 2000). In the current study, we define *perceived organizational politics* as an individual's perceptions of others' self-interested acts or behaviors; these acts are frequently associated with the manipulation of organizational policies and often include coercive tactics even at the expense of others for short-term gains (Kacmar & Ferris, 1991). These behaviors are perceived as subversive and contradict with the interests of other individuals and the organization (Vigoda, 2000).

As an antecedent to workplace outcomes, POP has generally been regarded as a stressor. For example, while examining stressors, Cavanaugh, Boswell, Roehling, and Boudreau (2000) found that POP loaded on a factor called *hindrance stressors*. The organizational development literature also conceives of perceived politics as a stressor that has a detrimental impact on a person's resources. More specifically, Crawford, Lepine, and Rich (2010) suggest that POP activates an energy depletion process whereby an employee's sustained increases in effort to meet perceived demands is met with an increase in compensatory actions and psychological processes that drain a person's individual resources. In addition, Chang et al. (2009) meta-analytically examined perceptions of politics as a hindrance stressor to find a stress-related connection to performance. In light of these findings, POP is regarded as a hindrance stressor in the present examination.

Despite recent meta-analytic evidence for variation in the effects of POP on outcomes (e.g., Miller et al., 2008), perceived politics can be summarized as having a generally positive relationship with turnover intentions (Chang et al., 2009) and a negative relationship with job satisfaction (Chang et al., 2009; Ferris & Kacmar, 1992) and job performance (Vigoda, 2000). There is also some evidence for the harmful effects of POP across cultures. For example, Vigoda (2001) found that British and Israeli employees reported similar levels of organizational politics in the workplace; however, British employees responded to perceived politics with higher turnover intentions than did Israeli employees. Vigoda (2001) attributed these findings to the difference in power distance between both cultures.

Britain ranks higher on the national cultural dimension of power distance as compared to Israel (Hofstede, 1983). In high power distance cultures, individuals usually accept a hierarchical order in which everybody has a place. In these cultures, interpersonal conflict is considered a disruption of ordinary life (Hofstede, 1991). Similar to Britain, Pakistan ranks high on power distance (Hofstede, 1983). In addition, Pakistan scores high on uncertainty avoidance, reacting adversely to uncertainty or a lack of control. Hofstede (2001) suggests that the combination of these two dimensions results in situations where leaders have ultimate power and authority and that rules, laws, and regulations are developed to reinforce such leadership. In such a context, formal rules and regulations exist to further managerial interests

at the expense of subordinates (Kacmar & Ferris, 1991), prompting turnover and lower job satisfaction as employees' reactions to perceived politics in the workplace. Hence, we expect to replicate the findings that perceived politics has harmful effects on outcomes in Pakistan.

Hypothesis 1: Perceived organizational politics will be positively related to turnover intentions and negatively related to job satisfaction and job performance.

Lately, researchers in the domain of positive organizational behavior have stressed the need to focus on the positive strengths and well-being of individuals in the workplace (Luthans & Youssef, 2007). These positive psychological approaches have emerged with a focus on what is right with people rather than on the traditional approaches of what is wrong with people (Luthans, 2002). This line of thinking has resulted in the coining of the term *psychological capital* (Avey, Luthans, & Youssef, 2010).

Although PsyCap is composed of four components—hope, optimism, self-efficacy, and resilience (Luthans, Youssef, & Avolio, 2007)—research considers hope and efficacy to be the most significant in predicting various work-related outcomes (e.g., Luthans, Avolio, Avey, & Norman, 2007; Stajkovic & Luthans, 1998a; Youssef & Luthans, 2007). Efficacy is “the employee’s conviction or confidence about his or her abilities to mobilize the motivation, cognitive resources, or courses of action needed to successfully execute a specific task within a given context” (Stajkovic & Luthans, 1998b: 66). Similarly, hope is “a positive motivational state that is based on an interactively derived sense of successful (a) agency (goal-directed energy) and (b) pathways (planning to meet goals)” (Snyder, Irving, & Anderson, 1991: 287).

Conceptually, self-efficacy and hope are assumed to be more significant factors than optimism and resiliency in predicting attitudes and organizational behavior (Bandura, 2012). Self-efficacy is considered to best meet the inclusion criteria for PsyCap in positive organizational behavior (Luthans, 2002). Similarly, of the three remaining facets of PsyCap, hope is the strongest predictor of work-related outcomes and shares the strongest underlying common denominator with self-efficacy (Luthans, 2002; Magaletta & Oliver, 1999; Youssef & Luthans, 2007). Efficacy and hope share the components of internalized motivation and energy, or the positive expectation of success for the reason of belief in one’s individual abilities. Highly efficacious and hopeful employees set challenging goals for themselves and self-select into challenging assignments with motivation and tenacious effort toward success. Therefore, we focus on the efficacy and hope dimensions of PsyCap in this study.

Previous research has found PsyCap to be positively associated with job performance and satisfaction (Luthans, Avolio, et al., 2007) and negatively associated with organizational cynicism and turnover intentions (Avey et al., 2010). Based on its definition, individuals with high PsyCap are believed to possess the cognitive capacity of self-regulation (Bandura, 1997) that offers the initiative, energy, and self-discipline necessary to reach one’s goals (Luthans & Youssef, 2007). Thus, we believe that being personal and psychological in nature, PsyCap will have similar effects on outcomes as those observed in U.S. settings. PsyCap, especially hope and self-efficacy, gives individuals more confidence and stimulates positive thinking, which should result in better performance, higher satisfaction, and lower possibility of leaving the job. Therefore, we suggest,

Hypothesis 2: Psychological capital will be negatively related to turnover intentions and positively related to job satisfaction and job performance.

The Moderating Role of PsyCap

Recent studies have shown the relevance of COR theory as a conceptual foundation for the role of individuals' psychological resources to cope with harmful effects of organizational politics (Kapoutsis, Papalexandris, Nikolopoulos, Hochwarter, & Ferris, 2011). Hindrance stressors tend to dampen motivation, which thwarts performance and personal goal attainment and growth (LePine, Podsakoff, & LePine, 2005). This theory helps in delineating the processes by which resources such as PsyCap assist individuals in coping with stressors. Individuals who possess key resources such as hope and self-efficacy "might be more capable of selecting, altering, and implementing their other resources to meet stressful demands" (Hobfoll, 2002: 308).

When faced with an environmental stressor (e.g., organizational politics), individuals exert efforts to successfully cope with it in order to maintain a balance (Hobfoll, 2011). The success of these efforts depends on the psychological resources these individuals possess (Treadway et al., 2005). Therefore, individual differences in internal psychological resources are likely to play an influential role in the attribution of resource loss as salient. Here, *resource loss* could refer to a perceived loss of tangible goals due to politics in the workplace or to a perceived loss of cognitive or emotional coping resources dedicated to addressing politics as a stressor.

We argue that high PsyCap individuals, because of their level of confidence in pursuing challenging tasks (Bandura, 1997), their capacity to derive multiple pathways to be successful (Snyder, 1994), and their ability to persevere in the face of obstacles (Stajkovic & Luthans, 1998a), are less likely to perceive organizational politics as threatening or harmful. These individuals possess the cognitive capacity of self-regulation (Bandura, 1997) that offers the initiative, proactiveness, and self-discipline necessary to reach the desired goals, even when there is a lack of extrinsic motivators (Luthans & Youssef, 2007) and absence of feedback (Judge, Jackson, Shaw, Scott, & Rich, 2007). Therefore, they are less likely to experience the typical negative outcomes (e.g., lowered job satisfaction and performance) associated with organizational politics.

Seligman and Csikszentmihalyi (2000) posit that hope plays the role of a buffering agent against psychological distress, addiction, and dysfunctional behavior. Studies have demonstrated a strong relationship between hope and academic and athletic performance, mental and physical health, and the ability to cope with adversity (Snyder, 1994; Snyder et al., 1991). Similarly, Caprara, Barbaranelli, Pastorelli, and Cervone (2004) investigated the ability of efficacy beliefs to predict psychosocial outcomes among high school students. These authors found that self-efficacy beliefs predicted lower problem behaviors (depression and aggression) and attainment of greater grades. Moreover, high efficacious individuals are less likely to expect failures or loss of confidence when faced with negative feedback, setbacks, uncertainties, and difficulties (Bandura & Locke, 2003).

When combined, these psychological resource capacities form the cognitive, emotional, and motivational bases (Bandura & Locke, 2003; Seligman & Csikszentmihalyi, 2000) through which individuals mitigate the detrimental effects of negativity (Youssef & Luthans, 2007). Based on these arguments, we believe that when individuals perceive organizational activities and procedures to be politically driven, their PsyCap may help them minimize the salience of resource loss associated with these activities, allowing them to cope better with these stressors, thereby reducing the influence of POP on outcomes. Consequently, we suggest,

Hypothesis 3: Psychological capital will moderate the relationship between perceived politics and outcomes (turnover intentions, job satisfaction, and job performance) such that the relationship will be weaker when psychological capital is high.

Method

Sample and Data Collection Procedures

Perceptions of politics can vary considerably across organizations. To capture maximum variance in politics, we decided to collect data from a variety of organizations. Through the personal and professional contacts of the first author, we were able to gain access to employees in six branches of private banks, local offices of two textile manufacturing firms, three offices of a government ministry, and customer service offices of a telecommunication company in Faisalabad, which is the third largest city of Pakistan. We decided to target all white-collar employees in each location for two reasons. First, we believe that organizational politics is more likely to play a role among managers and professional workers because they have to manage people and resources. Second, due to low education levels, we believe that lower level blue-collar workers would not be able to respond to a questionnaire in English effectively.

We collected data through onsite administration of a questionnaire with self- and supervisor-report versions. A cover letter explained the purpose of the study to the respondents, assured them of the strictest confidentiality of responses, and mentioned that participation was voluntary. Respondents completed the self-report version that contained items related to POP, PsyCap, turnover intentions, and job satisfaction. In addition, each respondent reported his or her name, age, gender, occupational level, education, and work experience in the demographics part of the survey. The supervisor of each respondent completed the supervisor-report version that contained questions on job performance. Both the respondents and their supervisors returned the completed questionnaires to one of the authors without having access to each other's responses. Each supervisor knew his or her subordinate for more than six months and had done at least one performance appraisal for that subordinate.

Of the 300 distributed questionnaires, we received 237 completed self-report responses. We were able to get supervisor reports from 79 supervisors for 231 of the respondents. Therefore, our final response rate for the 231 usable paired (231 employee and 231 supervisor responses) responses was 77%. We distributed 48 surveys among the government workers, 154 in bank branches, 33 in the telecom company, and 65 in the textile firms. The response rates for government offices, banks, telecom, and textile firms were 75%, 78%, 76%, and

75%, respectively. The majority of respondents (80.1%) were male with an average age of 31 years ($SD = 8.1$). The sample included several occupational levels comprising 16% entry-level (clerical and information technology) workers, 80% supervisors and middle managers, and 4% upper middle and top-level managers. The average tenure was 4.80 ($SD = 6.48$) years. About 31% of the respondents had an undergraduate university degree, while 69% held graduate degrees.

A total of 79 supervisors reported for the 231 respondents, which could result in nesting of data. With supervisor as a grouping variable, we ran the null model in hierarchical linear modeling (HLM) to calculate between- and within-group variance for job performance in our data set. This procedure estimated whether it was feasible to run a more complex model controlling for nesting of data based on supervisor as the higher order level in our data set. The results revealed that within-group variance ($R^2 = .27$) was substantially higher than between-group variance ($R^2 = .08$), and the F statistic for the ratio of the two variances was not significant, $F(78, 152) = .22, ns$. Put differently, the data suggest that supervisors as a grouping variable do not explain sufficient variance to justify the use of HLM analysis controlling for nesting of data (Bryk & Raudenbush, 1992).

Measures

All constructs were measured using self-reported instruments except for job performance, which was measured using supervisory ratings in order to avoid method bias issues. Responses for all variables, with the exception of PsyCap, were assessed using a 5-point Likert-type scale with the anchors 1 = *strongly disagree*, 2 = *disagree*, 3 = *neither disagree/nor agree*, 4 = *agree*, and 5 = *strongly agree*. The responses for PsyCap were measured using a 6-point Likert-scale with the anchors 1 = *strongly disagree*, 2 = *disagree*, 3 = *somewhat disagree*, 4 = *somewhat agree*, 5 = *agree*, and 6 = *strongly agree*. For all measures, higher scores corresponded to higher levels of the construct.

Perceptions of organizational politics (POP). We used the 12-item Perceptions of Organizational Politics Scale by Kacmar and Ferris (1991) to assess this construct. This scale contains three subdimensions of perceived politics: general political behavior (6 items), go along to get ahead (4 items), and pay and promotion policies (2 items). Examples of items include “People build themselves up by tearing others down” for the first dimension, “Employees are encouraged to speak out” (reverse coded) for the second, and “Pay and promotion policies are not politically applied” (reverse coded) for the third dimension.

As we were interested in examining the effects of overall perceived politics on outcomes, we conducted a second-order confirmatory factor analysis (CFA) to see if the three-dimensional construct did load on to a single latent factor. The results of CFA revealed a good fit for a latent single factor model ($\chi^2 = 84.76$, $df = 53$; comparative fit index [CFI] = .94, goodness-of-fit index [GFI] = .94, incremental fit index [IFI] = .95, and root mean square error of approximation [RMSEA] = .05). Therefore, we used an additive measure by taking the average of all items to create overall POP such that high scores reflected high perceived politics.¹ This treatment of the POP measure has been used in past research (e.g., Randall,

Cropanzano, Bormann, & Birjulin, 1999; Rosen, Levy, & Hall, 2006). Cronbach's alpha reliability of the POP measure was .73.

Psychological capital (PsyCap). We measured efficacy and hope using 12 items (6 items for each measure) from the Psychological Capital Questionnaire (Luthans, Youssef, et al., 2007). Examples of items include, "If I should find myself in a jam at work, I could think of many ways to get out of it" for hope and "I feel confident analyzing a long-term problem to find its solution" for efficacy. We conducted a second-order CFA to see if both hope and efficacy loaded onto a single latent factor. Results yielded a good fit for a latent single factor model ($\chi^2 = 102.91$, $df = 52$; CFI = .95, GFI = .94, IFI = .95, RMSEA = .06). Therefore, to create overall PsyCap, we averaged scores on all 12 items such that a high score reflected high PsyCap. The internal consistency reliability of PsyCap was .89.

Outcomes. A three-item scale by Vigoda (2000) was used to measure turnover intentions. This measure included items such as "I often think about quitting this job." The reliability of this measure was .76. We measured overall job satisfaction using a six-item scale developed by Agho, Price, and Mueller (1992), which contained questions such as "I feel fairly well satisfied with my present job" and "I find real enjoyment in my work." The reliability of this measure was .67. Supervisor responses to a seven-item scale developed by Williams and Anderson (1991) were used to measure job performance. Sample items include, "This person adequately completes assigned duties" and "This person performs tasks that are expected of him/her." The alpha reliability was .77.

Control variables. We used age and tenure as control variables because of their possible effects on job outcomes. A one-way ANOVA comparing job satisfaction, job performance, and turnover intentions across gender, education, and organizations revealed that there were significant differences in turnover intentions ($F = 34.02$, $p < .000$) and job satisfaction ($F = 14.60$, $p < .000$) across organizations. Post hoc analyses showed that the differences were only between the two groups of organizations in the public and private sectors. Hence, we used a dummy variable (0 = *private*, 1 = *public*) to control for the effects of organization type.

Results

POP, PsyCap, and Outcomes

Table 1 shows the descriptive statistics, bivariate correlations, and estimates of reliability (coefficient α) for all measures. All the zero-order bivariate correlations were in the expected direction.

We used multiple linear regression analyses to test all main effect hypotheses (Hypotheses 1 and 2). We entered age, tenure, and organizational type in the first step, followed by the independent variables. Table 2 (Step 3) presents the results for the main effects of POP and PsyCap on the outcomes. POP was positively related to turnover intention ($\beta = 0.26$,

Table 1
Means, Standard Deviations, Correlations, and Reliabilities

	<i>M</i>	<i>SD</i>	1	2	3	4	5	6	7	8
1. Age	30.82	8.10	—

p* < .05. *p* < .01. ****p* < .001.

p < .001) and negatively to job satisfaction ($\beta = -0.29$, *p* < .001) and job performance ($\beta = -0.21$, *p* < .05). These results support Hypothesis 1. Similarly, Table 2 shows that PsyCap was positively related to job satisfaction ($\beta = 0.56$, *p* < .001) and job performance ($\beta = 0.54$, *p* < .001), but its relationship with turnover intentions ($\beta = -0.01$, *ns*) was not significant. These results render support to Hypothesis 2 for satisfaction and performance only.

Moderating Influence of PsyCap

We used moderated multiple regression analyses (Cohen, Cohen, West, & Aiken, 2003) to test Hypothesis 3. We entered the control variables in the first step, followed by the independent and moderator variables in the next step. In the third step, we entered a product term of the independent and moderator variables, which if significant, confirmed moderation. We centered the variables by subtracting the overall mean from the individual values for the moderated regression analyses. In addition, we obtained the variance inflation factor (VIF) scores (Hair, Anderson, Tatham, & Black, 1998) and the tolerance statistics (Tabachnick & Fidell, 2001), which measure the extent to which collinearity among predictors affects the precision of a regression model. VIF scores of less than 5 (Chatterjee & Price, 1991) and tolerance scores above .10 (Hair et al., 1998) are typically considered acceptable. The VIF scores were below 3 (tolerance > .3) in all analyses, indicating that multicollinearity was not a problem.

Results presented in Table 2 (Step 3) show that, controlling for the effects of POP and PsyCap, the interaction term of POP \times PsyCap was significant for turnover intentions ($\beta = 0.14, p < .05; \Delta R^2 = .02, p < .05$), job performance ($\beta = 0.33, p < .001; \Delta R^2 = .09, p < .001$), and job satisfaction ($\beta = 0.17, p < .01; \Delta R^2 = .02, p < .01$). The additional variance explained by the interaction term falls within or exceeds the typical range for moderator effects in nonexperimental field studies (e.g., Chaplin, 1991).

We plotted the significant interactions for high and low ($M \pm SD$) values of the moderator. The plots of the significant interactions are displayed in Figures 1 through 3. Figure 1 shows that, contrary to our hypothesis, the positive POP–turnover intentions relationship was stronger when PsyCap was high. Simple slope tests using the procedure recommended by Aiken and West (1991) revealed that the slope for high levels of PsyCap was significant ($\beta = 0.79, p < .001$); however, the slope for low levels of PsyCap was not significant ($\beta = -0.23, ns$). Figure 2 shows the plot of the significant interaction for job satisfaction. The slope for high PsyCap was not significant ($\beta = -0.04, ns$), but the slope line for low PsyCap was significant ($\beta = -0.74, p < .01$). Figure 3 shows the plot of simple slopes for job performance. The relationship between perceived politics and job performance was significantly negative for low levels of PsyCap ($\beta = -1.26, p < .001$) and significantly positive for high levels of PsyCap ($\beta = 0.32, p < .01$). Hence, the results supported Hypothesis 3 for job performance and job satisfaction only.

Figures 2 and 3 indicate that there was one outlier cell, where PsyCap was low and POP was high, that tended to have greater effects. Therefore, we conducted the Bobko procedure (Bobko, 1986) as a robustness check for ordinal interaction effects. The results for the first contrast (comparing means for low POP and high PsyCap, for low POP and low PsyCap, and for high POP and high PsyCap) using a one-way analysis of variance showed that there were no significant differences between the three means ($F_{\text{performance}} = 1.59, ns; F_{\text{satisfaction}} = 1.64, ns$). The second contrast revealed that these three conditions were significantly different from the condition in which respondents were scoring high on POP and low on PsyCap ($t_{\text{performance}} = 5.19, p < .001; t_{\text{satisfaction}} = 4.49, p < .001$).

Discussion

Despite general agreement among researchers, empirical evidence has revealed variations in the influence of POP on outcomes. In this research, we not only tested for the moderating role of PsyCap in accounting for some of the observed variation in effects but also incorporated the COR theoretical framework to better understand how the psychological capital of hope and efficacy can play a role in employee efforts to address POP as a hindrance stressor.

Our findings clearly support the assertion that when employees perceive politics in the workplace, it reduces their satisfaction and performance and increases the likelihood of their leaving the organization. These findings provide support for the idea of perceived politics being detrimental to desired outcomes at the workplace. The results of our study also support the idea that PsyCap has a positive effect on desired outcomes such as job satisfaction and job performance, but not on intentions to quit. In addition, we found good support for the moderating influence of PsyCap in the POP–outcomes relationship. Interestingly, and contrary to our expectations, the negative relationship between perceived politics and intentions to quit was stronger when PsyCap was high. In retrospect, it is possible that individuals with high PsyCap, being more skillful and confident, think of leaving their jobs if they perceive high politics. They might want to seek a better working environment and start looking for options in the wake of high-perceived politics.

For example, it has been suggested that high performers are more likely to quit when salaries and promotion policies are not aligned (Allen & Griffeth, 1999), as they have greater

tangible resources such as a proven performance track record or other employment opportunities to draw upon (Jackofsky, 1984). Moreover, research on employability suggests that an organizational environment that does not foster its members' development and employability increases employees' turnover intentions (Nauta, van Vianen, van der Heijden, van Dam, & Willemsen, 2009). Our findings suggest that psychological resources function the same way, equipping individuals with the cognitive and emotional resources necessary to push them away from a threatening political workplace.

The results for the moderating effects of PsyCap in the relationship between POP and job satisfaction and performance were in the expected direction. In both cases, the observed negative relationship was stronger when PsyCap was low. The results indicate that POP is going to be a bigger concern for those with low PsyCap. Perceived politics does not seem to have a negative impact on the satisfaction and performance of individuals with high psychological resources (i.e., hope and efficacy).

Our finding that PsyCap comprising hope and efficacy acts as a threat neutralizer by reducing the negative effects of politics on performance deserves further attention, as it apparently contradicts with the findings of Kacmar et al. (2009). Drawing upon trait activation theory, Kacmar et al. (2009) found that core self-evaluations (which include generalized self-efficacy) intensified the deleterious effects of perceived politics on job performance. We believe that efficacy in conjunction with hope creates a positive resource for individuals that help them to take up the challenge of perceived politics instead of reacting negatively to it. Social psychologists argue that these psychological resources should be studied collectively, as they do not act in isolation (Fredrickson, 2001; Youssef & Luthans, 2007). Instead, such resources together provide support to each other through a shared underlying mechanism (Luthans, Avolio, et al., 2007) that binds them and helps individuals to use them effectively when faced with stressful situations (Hobfoll, 2002). More specifically, a person with no hope and high efficacy is less likely to effectively deal with hurdles as compared with an individual who not only has the required confidence but also has hope that his or her efforts will lead to positive outcomes. We believe that our findings support this line of thought and confirm the idea that efficacy and hope together act to minimize the harmful effects of POP on job outcomes.

A comparison of the zero-order correlations reported in Table 1 against the meta-analytic uncorrected associations reported by Miller et al. (2008) provides an opportunity to compare results for main effects in Western cultures to those examined in this study. With respect to turnover intentions and job performance, it appears that our obtained associations ($r = .30$ for turnover intentions and $r = -.08$ for job performance) are almost identical to those found for Miller et al.'s ($r = .33$ for turnover intentions and $r = -.09$ for job performance) domestic samples (i.e., North American, generally thought to be low on the cultural values of power distance and uncertainty). Although the perceived politics–satisfaction association was almost half the size ($r = -.21$) compared to that observed in Miller et al.'s meta-analysis for domestic samples ($r = -.40$), the confidence interval ($-.73$ to $-.17$) included the correlation observed in our study.

Taken together, these findings suggest that results from past research in the Western context generalize well to the Pakistani context. POP, perhaps, is much more personal in nature and less susceptible to contextual influences. This examination is consistent with the

call to examine theories, mostly developed and tested in Western settings, in a non-Western context. Our deliberate exploratory examination of cultural context is consistent with Johns's (2006) directions for future researchers in the field of organizational behavior. While this study provides some evidence for the external validity or generalizability of the examined relationships, it also points to the need for more direct examinations of context by incorporating discrete contextual features (e.g., cultural values) in future examinations of POP.

Implications for Practice

Our study provides some valuable managerial implications. For example, managers should be wary of the harmful implications of workplace politics. They should address potential contributors to POP, such as ambiguous policies and procedures, poor communication, and lack of proper feedback and guidance, to minimize the adverse effects on employees. Managers of organizations that are going through mergers, downsizing, or restructuring should be even more vigilant, as these processes also tend to increase uncertainty and politics in the work environment. It would be prudent for organizations to reexamine their selection criteria in hiring individuals, to include characteristics such as hope and efficacy, as these can buffer new hires from the influence of politics. The design and implementation of training interventions can benefit by incorporating methods that help in enhancing the psychological resources, especially hope and efficacy, of employees so that they are better equipped to cope with demanding and stressful work environments.

Strengths and Limitations

The current study has several strengths. First, responding to the call of Fineman (2006), this study integrates positive- and negative-oriented research. In particular, we enhance our understanding of the organizational politics and PsyCap theories in a new cultural setting significantly different from North America and Europe. Exploring the main and moderating effects in such a setting extends our understanding and provides evidence for the external validity of research dominated by Western samples. Second, we collected our field data from multiple sources, which reduced the possibility of method bias. Detection of significant interactions for self-reported perceived politics and supervisor-reported performance, where the interaction accounted for 9% additional variance, is rare. Third, this study provides strong evidence for the main effects of overall PsyCap on job satisfaction, and supervisor-rated job performance. Finally, our findings provide support for the role of PsyCap (i.e., hope and self-efficacy combined) as a threat neutralizer as compared with previous findings of efficacy as a threat amplifier.

This study has several limitations that need to be noted. One of the limitations has to do with common method bias. Although we attempted to circumvent this possibility by assessing job performance using supervisory ratings, this was not the case with the other examined variables. However, the obtained results for the main effects of POP are generally consistent when compared with those reported in past research. Moreover, significant interactions

suggest that method variance was not an issue, as it works against detection of such interaction effects. A second limitation is the slightly lower reliability of job satisfaction ($\alpha = .67$). Nevertheless, the obtained associations between POP and outcomes are consistent with the meta-analytic findings of Miller and colleagues (2008). A third limitation is that we included only two of the four dimensions of PsyCap. Although we do not expect our findings to change if the remaining two dimensions are included, because efficacy and hope are the dominant dimensions and have stronger effects, some differences in effect size cannot be ruled out.

Future Research Directions

Future research in this area should examine the role of other plausible individual and contextual moderators in the relationship between perceived politics and outcomes. For example, exploring the effects of the Big Five traits on the POP–outcomes relationship might provide insight into our understanding of the interplay of person and situation factors in determining various attitudinal and behavioral outcomes. Acknowledging possible differences in the domain of POP across nations, future research needs a direct comparison of non-Western and Western samples to explore the moderating influence of discrete cultural contextual factors (e.g., cultural values). Future studies should also focus on providing a more detailed analysis of the dimensionality of POP and its relative influence on job outcomes.

Similarly, research may continue to explore the viability and vitality of PsyCap as a construct that can help improve our understanding of organizational behavior. Being a statelike characteristic that is amenable to development, PsyCap may hold better promise for organizational effectiveness against the dominant trait theories. PsyCap, being a composite of positive psychological resources, has an inherent proactive coping mechanism and goal orientation that may buffer against challenge- and hindrance-related stressors such as role stressors, heavy workload, time pressure, and job scope. Testing models that directly examine such roles of PsyCap provides more insight into the buffering capacities of these resources.

Conclusion

Asia has an important role in the global economy, as multinationals are increasingly moving to Asian regions. Unless we test the theories largely developed in the United States in non-Western settings, researchers and practitioners would have little confidence about their generalizability in those regions (Tsui et al., 2007). Our study provides some insights into the generalizability of concepts such as POP and PsyCap in Pakistan. More efforts, however, are required to extend and test complex models in different cultural settings.

Note

1. We ran our analyses using a measure based on the mean of the means of dimensions. The results did not differ compared to the additive measure.
